

CBSE Class 12 Economics
NCERT Solutions
Chapter-02 (Macroeconomics)
National Income Accounting

1. What are the four factors of production and what are the remunerations to each of these called?

Ans: The four factors of production are:

- i. **Land-** Is a free gift of nature and is called as natural resources.. Land, therefore, includes all gifts of nature available to mankind-both on the surface and under the surface, e.g., soil, rivers, waters, forests, mountains, mines, deserts, seas, climate, rains, air, sun etc. It is considered as a primary factor of production.
- ii. **Labour-** Human effort done mentally or physically with the aim of earning income is known as labour. Thus, it is a physical or mental effort of human being engaged in the process of production. The compensation given to labourers in return for their productive work is called wages. Land is a passive factor whereas labour is an active factor of production.
- iii. **Capital-** Is the man-made goods which are used for further production of wealth. Thus it is man-made material source of production. Alternatively, all man-made aids to production which are not consumed for their own sake are termed as capital. In simple words goods that can be used or consumed in the production of other goods. Examples are- machines, tools, buildings, roads, bridges, factories etc.
- iv. **Entrepreneur-** An entrepreneur is a person who organizes the other factors and undertakes the risks and uncertainties involved in the production. He hires the other three factors, brings them together, organizes and coordinates them so as to earn maximum profit. For example- Mr. Z who takes the risk of manufacturing television sets will be called an entrepreneur.

The remunerations paid to the factors of production are called factor payments or factor incomes. These are the aggregation of rent, wage, interest and profit.

2. Why should the aggregate final expenditure of an economy be equal to the aggregate

factor payments? Explain.

Ans: In an economy, consisting of households and firms, the only way in which the households can dispose their income is on the goods and services produced by the firms. The factors of production use their remuneration to purchase goods and services. Thus, the income will come back to the producers in the form of sales' revenue. So, there is no difference between the amount that firms distribute in the form of factor payments and consumption expenditure incurred by the households. The same process continues year after year. However, if there has been any leakage in the form of savings, imports or taxes, then there arises a difference between the aggregate consumption expenditure and aggregate factor payments. In the case of some leakage, the households will spend less than their factor incomes. Consequently, the firms will receive lesser amount in the form of revenue, which will reduce the production level and employment level. This process will continue in every successive round and production and employment levels will continue to drop. Thus, the equality between the aggregate consumption expenditure and the aggregate factor payments is very necessary for the smooth functioning of the economy.

3. Distinguish between stock and flow. Between net investment and capital, which is a stock and which is a flow? Compare net investment and capital with flow of water into a tank.

Ans: Difference between stock and flow

	Stock		Flow
1.	Stock refers to the variable which can be measured at a particular point of time. For Example, bank balance on 31st of March 2017.	1.	The flow refers to the variables that are measured over a period of time. For example, interest earned on bank deposits for 1 year, i.e. from 1 April 2016 to 30 Sep 2017.
2.	It has no time dimensions.	2.	It has time dimensions, like 1 year, 6 months etc.
3.	Examples: Equity shareholdings, inventory, bank deposits, water in a tank etc.	3.	Examples: Sale of shares, purchase of shares, interest deposit, withdrawal, water flowing in a stream etc.

Difference between Net investment and Capital

	Stock		Flow
1.	Net investment is the amounts spend by a company or an economy on capital assets or gross investment less depreciation on assets.	1.	Capital is theman-made goods which are used for further production of wealth. The amount of investment for the process of production.
2.	Net investment is flow variable	2.	Capital is a stock variable

 Kopykitab
Same textbooks, knock away

The amount or level of water in a tank is a stock variable. At any point of time the amount or the level of water in a tank can be measured. Similarly, the capital is also a stock variable, as the capital can also be measured at any point of time.

Now, if water is flowing out of a tank through a tap, then the level of water will change over time. The difference in water level over an interval of time is an example of a flow variable. Similarly, net investment gives the difference in the investment level over a period of time.

4. What is the difference between planned and unplanned inventory accumulation?

Write down the relation between change in inventories and value added of a firm.

Ans: The stock of unsold goods (finished and semi-finished), which a firm carry forward from one year to another year is termed as an inventory.

Inventory accumulation can be planned or unplanned. The planned inventory accumulation refers to the inventory that a firm can anticipate or plan. For example, a firm want to raise its inventory from 2000 to 3000 units of denims and expects sales to be 10000 units. Thereby, it produces 10000 + 1000 units, i.e. 11000 units (in order to raise the inventory by 1000 units). If, at the end of the year it is found that the actual sales that got realised were also 10000, then the firm experiences the rise in its inventory from 2000 to 3000 units. The closing balance of inventory is calculated in the following manner:

Final Inventory = Opening inventory + Production - Sale

= 2000 + 11000 - 10000

= 3000 units of denims

In this case the inventory accumulation is equal to the expected accumulation. Hence, this is an example of a planned inventory accumulation.

Unplanned inventory accumulation is an unexpected change in an inventory. There is an unplanned accumulation in an inventory when the actual sales are unexpectedly low or high. For example, let us assume, a firm wants to raise inventory from Rs 2000 to 3000 and expects sales to be 10000 and thereby produces 11000 units of denims. If, at the end of the year, the actual sales realised were 9000 units only, which were not anticipated by the firm.

The unexpected inventory accumulation is calculated as:

$$\text{Final Inventory} = \text{Opening inventory} + \text{Production} - \text{Sale}$$

$$= 2000 + 11000 - 9000$$

$$= 4000 \text{ units of denims}$$

Hence, this is example of unexpected inventory accumulation.

The relation between value added and the change in inventory is shown by the given equation:

$$\text{Gross value added by a firm} = \text{Sales} + \text{Change in inventory} - \text{Value of intermediate goods}$$

It implies that, as inventory increases, the value added by a firm will also increase, thus confirming the positive relationship between the two.

5. Write down the three identities of calculating the GDP of a country by the three methods. Also briefly explain why each of these should give us the same value of GDP.

Ans: GDP can be calculated by the following three methods:

(a) Income method: Under this method national income is measured in terms of factors of production..

GDP = Total payments made to the factors of production

$$\text{GDP} = \sum_{i=1}^M W_i + \sum_{i=1}^M P_i + \sum_{i=1}^M I_i + \sum_{i=1}^M R_i \dots\dots\dots(i)$$

$\sum W_i$ represents total wages and salaries received by i -th households. represents

$\sum P_i$ total profit received by i -th households.

$\sum I_i$ represents total Income received by i -th households.

$\sum W_i$ represents total Rent received by i -th households.

Equation (1) can be simplified as

$$GDP = W + R + I + P$$

(b) Value added or product method : It is that method which measures the national income in terms of each producing enterprise in the economy.

GDP = Sum of gross value added by all firms in an economy

$$\text{or } GDP = GVA_1 + GVA_2 + \dots + GVA_n$$

Where,

GVA_1 represents gross value added by the 1st firm

GVA_2 represents gross value added by the 2nd firm and so on

GVA_n represents gross value added by the nth firm

Therefore,

$$GDP = \sum_{i=1}^n GVA_i$$

(c) Expenditure method or final consumption method:

Under this method national income is measured in terms of the expenditure on the purchase of final goods and services produced in the economy.

GDP = Sum total of revenues that firms earn

Or

GDP = Total consumption + Investment + Government Consumption expenditure + Net exports

$$= \sum_{i=1}^N C_i + \sum_{i=1}^N I_i + \sum_{i=1}^N G_i + \sum_{i=1}^N X_i$$

As households spend some part of their income on imports, some portion of consumption expenditure also comprises of imports, which are denoted by C_M . Similarly, some part of the investment expenditure and government consumption expenditure is spent on the

consumption expenditure are denoted by I_M and G_M respectively. Thus, the final households' consumption expenditure, investment expenditure and final government expenditure that are spent on the domestic firms are denoted by $C - C_M$, $I - I_M$ and $G - G_M$ respectively.

Substituting these values in the above equation

$$\begin{aligned} \text{GDP} &= C - C_M + I - I_M + G - G_M + \sum_{i=1}^M X_i \\ &= C + I + G + \sum_{i=1}^M X_i - (C_M + I_M + G_M) \\ &= C + I + G + X - M \end{aligned}$$

The three methods give the same result for measuring GDP because what is produced in the economy is either consumed or invested. The three methods depict the same picture of an economy from three different angles. While the product method presents the value added or total production, the income method depicts the income earned by all the factors, lastly, the expenditure method presents the expenditure incurred by all the factors. In the economy, the producer employs four factors of production to produce final goods and earns revenue by sale, which is equivalent to the total value addition by the firm. The firms pay remunerations to the factors, which act as the income of all the factors. These remunerations are equivalent to the factors' contributions to the value addition. These factor incomes are then expended on the goods and services, which verifies the equality between the factor income and expenditure. Hence, the three methods will always give the same value of GDP.

6. Define budget deficit and trade deficit. The excess of private investment over saving of a country in a particular year was Rs 2,000 crores. The amount of budget deficit was (-) Rs 1,500 crores. What was the volume of trade deficit of the country?

Ans: Budget Deficit

The excess of government expenditure over government income is termed as budget deficit.

$$\text{Budget Deficit} = G - T$$

Where,

'G' represents government expenditure

'T' represents government income

Trade deficit measures the excess of import expenditure over the export revenue of a country.

$$\text{Trade Deficit} = M - X \text{ or } (I-S) + (G-T)$$

Where

'M' represents expenditure on imports

'X' represents revenue earned by exports

'I' represents investment

'S' represents saving

It is given that,

$$I - S = \text{Rs.}2000 \text{ crores.}$$

$$G - T = (-) \text{Rs.}1500 \text{ crores.}$$

Therefore,

$$\text{Trade deficit} = [I - S] + [G - T]$$

$$= 2000 + [-1500]$$

$$= \text{Rs.}500 \text{ crores.}$$

7. Suppose the GDP at market price of a country in a particular year was Rs 1,100 crores. Net Factor Income from Abroad was Rs 100 crores. The value of Indirect taxes-Subsidies was Rs 150 crores and National Income was Rs 850 crores. Calculate the aggregate value of depreciation.

Ans: National Income $(NNP_{FC}) = \text{Rs.}850 \text{ crores}$

$$GDP_{MP} = \text{Rs.1100 crores}$$

Net factor income from abroad = Rs.100 crores

Net indirect taxes = Rs.150 crores

$$NNP_{FC} = GDP_{MP} + \text{Net factor income from abroad} - \text{Depreciation} - \text{Net indirect taxes}$$

Putting these values in the formula,

$$850 = 1100 + 100 - \text{Depreciation} - 150$$

$$850 = 1100 - 50 - \text{Depreciation}$$

$$850 = 1050 - \text{Depreciation}$$

Depreciation = $1050 - 850 = \text{Rs.200 crores}$ So,

depreciation is Rs.200 crores.

8. Net National Product at Factor Cost of a particular country in a year is Rs 1,900 crores. There are no interest payments made by the households to the firms/government, or by the firms/government to the households. The Personal Disposable Income of the households is Rs 1,200 crores. The personal income taxes paid by them is Rs 600 crores and the value of retained earnings of the firms and government is valued at Rs 200 crores. What is the value of transfer payments made by the government and firms to the households?

Ans: $NNP_{FC} = \text{Rs.1900 crores}$

PDI = Rs.1200 crores

Personal income tax = Rs.600 crores

Value of retained earnings = Rs.200 crores

$PDI = NNP_{FC} - \text{Value of retained earnings of firms and government} + \text{value of transfer payments} - \text{personal tax}$

$$1200 = 1900 - 200 + \text{Value of transfer payments} - 600$$

$$1200 = 1100 + \text{Value of transfer payments}$$

$$\text{Value of transfer payment} = 1200 - 1100 = \text{Rs } 100 \text{ crores}$$

9. From the following data, calculate Personal Income and Personal Disposable Income.

		Rs (Crore)
(a)	Net Domestic Product at factor cost	8,000
(b)	Net Factor Income from abroad	200
(c)	Undisbursed Profit	1,000
(d)	Corporate Tax	500
(e)	Interest Received by Households	1,500
(f)	Interest Paid by Households	1,200
(g)	Transfer Income	300
(h)	Personal Tax	500

Ans: Personal Income = NDP_{FC} + Net factor income from abroad (NFIA) + Transfer Income - Undistributed profit - corporate tax - Net interest paid by households

$$NDP_{FC} = \text{Rs. } 8000 \text{ crores}$$

$$\text{NFIA} = \text{Rs. } 200 \text{ crores}$$

$$\text{Transfer Income} = \text{Rs. } 300 \text{ crores}$$

$$\text{Undistributed profit} = \text{Rs. } 1,000 \text{ crores}$$

$$\text{Corporate tax} = \text{Rs. } 500 \text{ crores}$$

$$\text{Net interest paid by households} = \text{Interest paid} - \text{Interest received}$$

$$= 1200 - 1500$$

$$= (-) \text{Rs. } 300 \text{ crores}$$

So, putting the values in the above formula

$$PI = 8000 + 200 + 300 - 1000 - 500 - (-300)$$

$$= 8000 + 200 + 300 - 1000 - 500 + 300$$

$$PI = 7300$$

So, Personal Income = Rs.7300 crores

Personal Disposable income = Personal Income - Personal Payments

$$= 7300 - 500$$

$$= \text{Rs.}6800 \text{ crores}$$

10. In a single day Raju, the barber, collects Rs 500 from haircuts; over this day, his equipment depreciates in value by Rs 50. Of the remaining Rs 450, Raju pays a sales tax worth Rs 30, takes home Rs 200 and retains Rs 220 for improvement and buying of new equipment. He further pays Rs 20 as income tax from his income. Based on this information, complete Raju's contribution to the following measures of income (a) Gross Domestic Product (b) NNP at market price (c) NNP at factor cost (d) Personal income (e) Personal disposable income.

Ans:

$$\text{Indirect tax} = 30$$

$$\text{Personal tax} = 20$$

$$\text{Depreciation} = 50$$

$$\text{Retained earnings} = 220$$

$$\text{(i) } GDP_{MP} = \text{Rs.}500 \text{ [Barber collects from haircut]}$$

$$\text{(ii) } NNP_{MP} = GDP - \text{Depreciation}$$

$$= 500 - 50$$

$$= \text{Rs.}450$$

$$\text{(iii) } NNP_{FC} = NNP - \text{Sales tax}$$

$$= 450 - 30$$

$$= \text{Rs.}420$$

$$\text{(iv) } PI = NNP_{FC} - \text{Retained earnings}$$

$$= 420 - 220$$

$$= \text{Rs.}200$$

$$(v) \text{ PDI} = \text{PI} - \text{Income tax}$$

$$= 200 - 20$$

$$= \text{Rs.}180$$

11. The value of the nominal GNP of an economy was Rs 2,500 crores in a particular year. The value of GNP of that country during the same year, evaluated at the prices of same base year, was Rs 3,000 crores. Calculate the value of the GNP deflator of the year in percentage terms. Has the price level risen between the base year and the year under consideration?

Ans: Nominal GNP = Rs.2500

Real GNP = Rs.3000

$$\text{GNP deflator} = \frac{\text{Nominal GNP}}{\text{Real GNP}} \times 100$$

So,

$$\text{GNP deflator} = \frac{2500}{3000} \times 100$$

$$= 83.33\%$$

No, the price level has fallen down by 16.67 % [(100 - 83.33) %].

12. Write down some of the limitations of using GDP as an index of welfare of a country.

Ans: Limitations of using GDP as an indicator are as follows:

1. **Distribution of GDP:** It is possible that with rise in GDP, inequalities in the distribution of income may also increase, i.e. the gap between rich and poor increases. GDP does not take

into account changes in inequalities in the distribution of income. So, welfare of the people may not rise as much as the rise in GDP.

2. **Change in prices:** If increase in GDP is due to rise in prices and not due to increase in physical output, then it will not be reliable index of economic welfare.

3. **Non-monetary exchanges:** Many activities in an economy are not evaluated in monetary terms. For example- non-market transactions like services of housewife, kitchen gardening, leisure time activities etc. are not included in GDP, due to non-availability of data. However, such activities influence the economic welfare.

4. **Externalities:** Externalities refers to benefits or harms of an activity caused by a firm or an individual, for which they are not paid or penalised. Activities which results in benefits to others are termed as positive externalities and activities which result in harm to others are termed as negative externalities.

5. **Rate of population growth:** GDP does not consider the changes in the population of a country. If rate of population growth is higher than the rate of growth of GDP, then it will decrease the per capita availability of goods and services, which will adversely affect the economic welfare.

Finally, it can be concluded that GDP may not be taken as a satisfactory measure of economic welfare due to above mentioned limitations, yet it does reflect some index of economic welfare.
