### Complex numbers Ex 13.1 Q1(i)

We know that  $i = \sqrt{-1}$

$$i^2 = -1$$

$$i^3 = -i$$

$$i^4 = 1$$

In order to find  $i^n$  where  $n > 4$ , we divide  $n$  by 4 to get quotient  $p$  and remainder  $q$ , so that  
$$n = 4p + q, 0 \leq q < 4$$

Then  $i^n = i^{4p+q}$

$$= i^{4p} \times i^q$$

$$= (i^4)^p \times i^q$$

$$= 1^p \times i^q$$

$$= i^q \quad [\because 1^{p-1}]$$

Hence  $i^n = i^q$ , where  $0 \leq q < 4$

$$\therefore i^{457} = i^{4 \times 114} \times i^1$$

$$= i^1$$

$$= i$$

### Complex numbers Ex 13.1 Q1(ii)

We know that  $i = \sqrt{-1}$

$$i^2 = -1$$

$$i^3 = -i$$

$$i^4 = 1$$

In order to find  $i^n$  where  $n > 4$ , we divide  $n$  by 4 to get quotient  $p$  and remainder  $q$ , so that  
$$n = 4p + q, 0 \leq q < 4$$

Then  $i^n = i^{4p+q}$

$$= i^{4p} \times i^q$$

$$= (i^4)^p \times i^q$$

$$= 1^p \times i^q$$

$$= i^q \quad [\because 1^{p-1}]$$

Hence  $i^n = i^q$ , where  $0 \leq q < 4$

$$\therefore i^{528} = i^{4 \times 132}$$

$$= (i^4)^{132}$$

$$= 1^{132}$$

$$= 1$$

$$\therefore (i^{528}) = 1$$

### Complex numbers Ex 13.1 Q1(iii)

We know that  $i = \sqrt{-1}$

$$i^2 = -1$$

$$i^3 = -i$$

$$i^4 = 1$$

$$= i^{4p} \times i^q$$

$$= (i^4)^p \times i^q$$

$$= 1^p \times i^q$$

$$= i^q \quad [\because 1^{p-1}]$$

Hence  $i^n = i^q$ , where  $0 \leq q < 4$

$$\therefore \frac{1}{i^{58}} = \frac{1}{i^{4 \times 14} \times i^2}$$

$$= \frac{1}{1 \times i^2}$$

$$= \frac{1}{-1} \quad [\because i^2 = -1]$$

$$= -1$$

We know that  $i = \sqrt{-1}$

$$= 1^p \times i^q$$

$$= i^q \quad [\because 1^{p-1}]$$

Hence  $i^n = i^q$ , where  $0 \leq q < 4$

$$\begin{aligned} \therefore i^{37} + \frac{1}{i^{67}} &= i^{4 \times 9} \times i^1 + \frac{1}{i^{4 \times 16} \times i^3} \\ &= 1 \times i^1 + \frac{1}{1 \times i^3} \\ &= i + \frac{1}{i^3 \times i} \\ &= i + \frac{i}{i^4} \\ &= i + \frac{i}{1} \quad [\because i^4 = 1] \\ &= 2i \end{aligned}$$

$$\therefore i^{37} + \frac{1}{i^{67}} = 2i$$

We know that  $i = \sqrt{-1}$

$$= 1^p \times i^q$$

$$= i^q \quad [\because 1^{p-1}]$$

Hence  $i^n = i^q$ , where  $0 \leq q < 4$

$$\begin{aligned} \left(i^{41} + \frac{1}{i^{257}}\right)^9 &= \left(i^{4 \times 10} \times i^1 + \frac{1}{i^{4 \times 64} \times i^1}\right)^9 \\ &= \left(1 \times i + \frac{1}{1 \times i}\right)^9 \\ &= \left(i + \frac{1}{i}\right)^9 \\ &= \left(i + \frac{1}{i \times i} \times i\right)^9 \\ &= \left(i + \frac{i}{-1}\right)^9 \\ &= (i - i)^9 \\ &= 0 \end{aligned}$$

We know that  $i = \sqrt{-1}$

$$i^2 = -1$$

$$i^3 = -i$$

$$i^4 = 1$$

Hence  $i^n = i^q$ , where  $0 \leq q < 4$

$$\begin{aligned}(i^{77} + i^{70} + i^{87} + i^{414})^3 &= (i^{4 \times 19} \times i^1 + i^{4 \times 17} \times i^2 + i^{4 \times 21} \times i^3 + i^{4 \times 103} \times i^2)^3 \\ &= (1 \times i + 1 \times i^2 + 1 \times i^3 + 1 \times i^2)^3 \\ &= (i - 1 - i - 1)^3 \\ &= (-2)^3 \\ &= -8\end{aligned}$$

### Complex Numbers Ex 13.2 Q2(i)

$$\text{We have } (x + iy)(2 - 3i) = 4 + i$$

$$\Rightarrow x(2 - 3i) + iy(2 - 3i) = 4 + i$$

$$\Rightarrow 2x - 3xi + 2yi + 3y = 4 + i$$

$$\Rightarrow 2x + 3y + i(-3x + 2y) = 4 + i$$

Equating the real and imaginary parts we get

$$2x + 3y = 4 \dots\dots\dots(i)$$

$$-3x + 2y = 1 \dots\dots\dots(ii)$$

Multiplying (i) by 3 and (ii) by 2 and adding

$$6x - 6x - 9y + 4y = 12 + 2$$

$$\Rightarrow 13y = 14$$

$$\Rightarrow y = \frac{14}{13}$$

Substituting the value of  $y$  in (i), we get

$$2x + 3 \times \frac{14}{13} = 4$$

$$\Rightarrow 2x + \frac{42}{13} = 4$$

$$\Rightarrow 2x = 4 - \frac{42}{13}$$

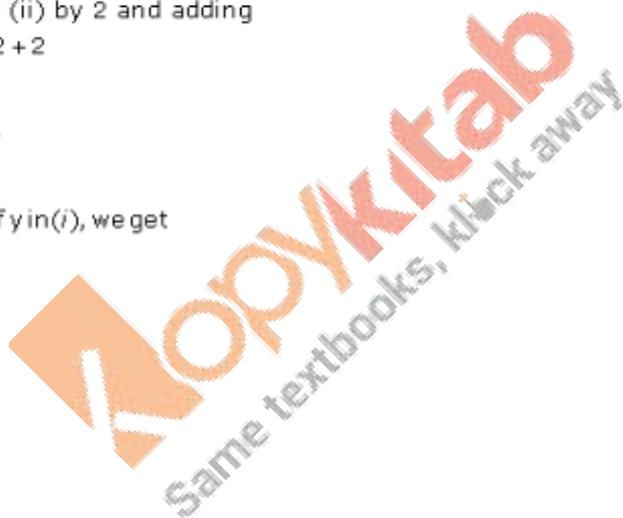

$$\Rightarrow 2x = \frac{52 - 42}{13}$$

$$\Rightarrow 2x = \frac{10}{13}$$

$$\Rightarrow x = \frac{5}{13}$$

Hence

$$x = \frac{5}{13} \text{ and } y = \frac{14}{13}$$

$$(3x - 2iy)(2 + i)^2 = 10(1 + i)$$

$$\Rightarrow (3x - 2iy)(2^2 + i^2 + 2 \times 2 \times i) = 10 + 10i$$

$$\Rightarrow (3x - 2iy)(4 - 1 + 4i) = 10 + 10i$$

$$\Rightarrow 3x(3 + 4i) - 2iy(3 + 4i) = 10 + 10i$$

$$\Rightarrow 9x + 12xi - 6yi + 8y = 10 + 10i$$

$$\Rightarrow 9x + 8y + i(12x - 6y) = 10 + 10i$$

Equating the real and imaginary parts we get

$$9x + 8y = 10 \dots\dots\dots (i)$$

$$12x - 6y = 10 \dots\dots\dots (ii)$$

Multiplying (i) by 6 and (ii) by 8 and adding

$$54x + 96y + 48y - 48y = 60 + 80$$

$$\Rightarrow 150x = 140$$

$$\Rightarrow x = \frac{140}{150}$$

$$\Rightarrow x = \frac{14}{15}$$

Substituting value of  $x$  in (i) we get

$$9 \times \frac{14}{15} + 8y = 10$$

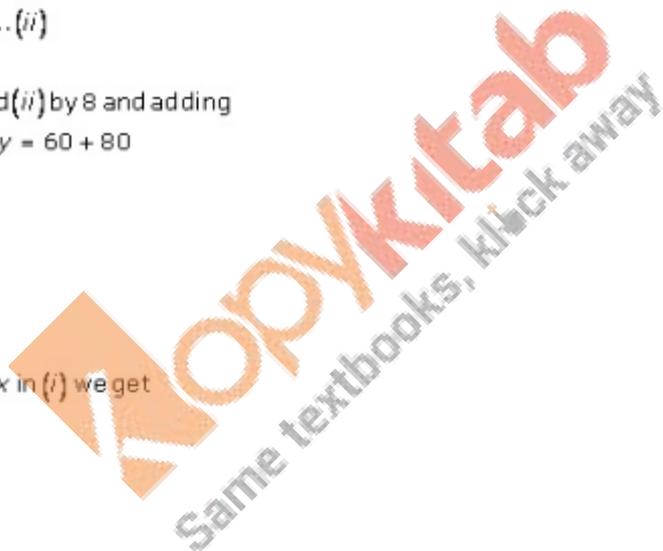

$$\Rightarrow \frac{42}{5} + 8y = 10$$

$$\Rightarrow 8y = 10 - \frac{42}{5}$$

$$\Rightarrow 8y = \frac{50 - 42}{5}$$

$$\Rightarrow 8y = \frac{8}{5}$$

$$\Rightarrow y = \frac{1}{5}$$

$$\frac{(1+i)x - 2i}{3+i} + \frac{(2-3i)y + i}{3-i} = i$$

$$\Rightarrow \frac{(3-i)((1+i)x - 2i) + (3+i)((2-3i)y + i)}{(3+i)(3-i)} = i$$

$$\Rightarrow \frac{(3-i)(1+i)x - 2i(3-i) + (3+i)(2-3i)y + i(3+i)}{3^2 + 1^2} = i$$

$$\Rightarrow \frac{(3+3i-i+1)x - 6i - 2 + (6-9i+2i+3)y + 3i - 1}{9+1} = i$$

$$\Rightarrow \frac{(4+2i)x - 6i - 2 + (9-7i)y + 3i - 1}{10} = i$$

$$\Rightarrow 4x + 2ix - 6i - 2 + 9y - 7iy + 3i - 1 = 10i$$

$$\Rightarrow 4x + 9y - 3 + i(2x - 7y - 3) = 10i$$

Equating real and imaginary parts we get

$$4x + 9y - 3 = 0 \dots\dots\dots (i)$$

$$\text{and } 2x - 7y - 3 = 10$$

$$i.e. 2x - 7y = 13 \dots\dots\dots (ii)$$

Multiplying (i) by 7, (ii) by 9 and adding we get

$$28x + 18x + 63y - 63y = 117 + 21$$

$$\Rightarrow 46x = 117 + 21$$

$$\Rightarrow 46x = 138$$

$$\Rightarrow x = \frac{138}{46}$$

$$= 3$$

Substituting the value of  $x = 3$  in (i), we get

$$4 \times 3 + 9y = 3$$

$$\Rightarrow 9y = -9$$

$$\Rightarrow y = \frac{-9}{9}$$

$$\Rightarrow y = -1$$

Hence

$$x = 3, y = -1$$

$$(1+i)(x+iy) = 2-5i$$

$$\Rightarrow 1(x+iy) + i(x+iy) = 2-5i$$

$$\Rightarrow x+iy+ix-y = 2-5i$$

$$\Rightarrow x-y+i(x+y) = 2-5i$$

Equating real and imaginary parts we get

$$x-y = 2 \dots\dots\dots (i)$$

$$x+y = -5 \dots\dots\dots (ii)$$

Adding (i) and (ii) we get

$$2x = 2-5$$

$$\Rightarrow 2x = -3$$

$$\Rightarrow x = \frac{-3}{2}$$

Substituting the value of  $x$  in (i), we get

$$\frac{-3}{2} - y = 2$$

$$\Rightarrow \frac{-3}{2} - 2 = y$$

$$\Rightarrow y = \frac{-3-4}{2}$$

$$\Rightarrow y = \frac{-7}{2}$$

Hence

$$x = \frac{-3}{2}, y = \frac{-7}{2}$$

### Complex Numbers Ex 13.4 Q1(vii)

The polar form of a complex number  $z = x + iy$ , is given by  $z = |z|(\cos \theta + i \sin \theta)$  where,

$$|z| = \sqrt{x^2 + y^2} \text{ and}$$

$$\arg(z) = \theta = \tan^{-1} \left( \frac{b}{a} \right)$$

$$\text{let } z = \sin 120^\circ - i \cos 120^\circ$$

$$= \sin \left( \frac{\pi}{2} + \frac{\pi}{6} \right) - i \cos \left( \frac{\pi}{2} + \frac{\pi}{6} \right) \quad (\because 120^\circ = \frac{\pi}{2} + \frac{\pi}{6})$$

$$\Rightarrow z = \cos \frac{\pi}{6} + i \sin \frac{\pi}{6} \quad \left( \because \sin \left( \frac{\pi}{2} + \theta \right) = \cos \theta \text{ \& } \cos \left( \frac{\pi}{2} + \theta \right) = -\sin \theta \right)$$

Here  $z$  is already in polar form

The polar form of a complex number  $z = x + iy$ , is given by  $z = |z|(\cos \theta + i \sin \theta)$

where,

$$|z| = \sqrt{x^2 + y^2} \text{ and}$$

$$\arg(z) = \theta = \tan^{-1}\left(\frac{b}{a}\right)$$

$$\begin{aligned} \text{let } z &= \frac{-16}{1+i\sqrt{3}} \\ &= \frac{-16}{1+i\sqrt{3}} \times \frac{1-i\sqrt{3}}{1-i\sqrt{3}} \\ &= \frac{-16(1-i\sqrt{3})}{(1)^2 + (\sqrt{3})^2} \\ &= \frac{-16(1-i\sqrt{3})}{1+3} \\ &= \frac{-16}{4}(1-i\sqrt{3}) \\ &= -4(1-i\sqrt{3}) \\ &= -4 + 4\sqrt{3}i \end{aligned}$$

$$\begin{aligned} \therefore |z| &= \sqrt{(-4)^2 + (4\sqrt{3})^2} \\ &= \sqrt{16 + 48} \\ &= \sqrt{64} \\ &= 8 \end{aligned}$$

Here  $x = -4 < 0$  &  $y = 4\sqrt{3} > 0$ ,  $\therefore \theta$  lies in quadrant II

$$\begin{aligned} \theta = \arg(z) &= \tan^{-1}\left(\frac{4\sqrt{3}}{-4}\right) \\ &= \tan^{-1}(-\sqrt{3}) \\ &= \tan^{-1}\left(-\tan \frac{\pi}{3}\right) \\ &= \tan^{-1}\left(\tan\left(\pi - \frac{\pi}{3}\right)\right) \quad (\because \tan(\pi - \theta) = -\tan \theta) \\ &= \pi - \frac{\pi}{3} \\ &= \frac{2\pi}{3} \end{aligned}$$

The polar form is given by  $z = 8\left(\cos \frac{2\pi}{3} + i \sin \frac{2\pi}{3}\right)$

$$z = (i^{25})^3 = (i)^3 = -i$$

$$|z| = 1,$$

### Complex Numbers Ex 13.4 Q3(i)

$$\text{Let } z = 1 + i \tan \alpha$$

$\tan \alpha$  is periodic function with period  $\pi$

So, let us take  $\alpha$  lying in the interval  $\left[0, \frac{\pi}{2}\right) \cup \left(\frac{\pi}{2}, \pi\right]$ .

Case - I : When  $\alpha \in \left[0, \frac{\pi}{2}\right)$

$$|z| = \sqrt{1 + \tan^2 \alpha} = \sqrt{\sec^2 \alpha} = |\sec \alpha| = \sec \alpha$$

Let  $\beta$  be acute angle given by  $\tan \beta = \frac{|\operatorname{Im}(z)|}{|\operatorname{Re}(z)|}$ .

$$\tan \beta = |\tan \alpha| = \tan \alpha$$

$$\Rightarrow \beta = \alpha$$

As  $z$  is represented by a point in first quadrant.

$$\therefore \arg(z) = \beta = \alpha.$$

So polar form of  $z$  is  $\sec \alpha (\cos \alpha + i \sin \alpha)$

Case - II : When  $\alpha \in \left(\frac{\pi}{2}, \pi\right]$

$$|z| = \sqrt{1 + \tan^2 \alpha} = \sqrt{\sec^2 \alpha} = |\sec \alpha| = -\sec \alpha$$

Let  $\beta$  be acute angle given by  $\tan \beta = \frac{|\operatorname{Im}(z)|}{|\operatorname{Re}(z)|}$ .

$$\tan \beta = |\tan \alpha| = -\tan \alpha = \tan(\pi - \alpha)$$

$$\Rightarrow \beta = \pi - \alpha$$

As  $z$  is represented by a point in fourth quadrant.

$$\therefore \arg(z) = -\beta = \alpha - \pi$$

So polar form of  $z$  is  $-\sec \alpha (\cos(\alpha - \pi) + i \sin(\alpha - \pi))$ .

### Complex Numbers Ex 13.4 Q3(ii)

Let  $z = \tan\alpha - i$

$\tan\alpha$  is periodic function with period  $\pi$

So, let us take  $\alpha$  lying in the interval  $\left[0, \frac{\pi}{2}\right) \cup \left(\frac{\pi}{2}, \pi\right]$ .

Case - I : When  $\alpha \in \left[0, \frac{\pi}{2}\right)$

$$|z| = \sqrt{\tan^2\alpha + 1} = \sqrt{\sec^2\alpha} = |\sec\alpha| = \sec\alpha$$

Let  $\beta$  be acute angle given by  $\tan\beta = \frac{|\operatorname{Im}(z)|}{|\operatorname{Re}(z)|}$ .

$$\tan\beta = \frac{1}{|\tan\alpha|} = |\cot\alpha| = \cot\alpha = \tan\left(\frac{\pi}{2} - \alpha\right)$$

$$\Rightarrow \beta = \frac{\pi}{2} - \alpha$$

As  $z$  is represented by a point in fourth quadrant.

$$\therefore \arg(z) = -\beta = \alpha - \frac{\pi}{2}.$$

So polar form of  $z$  is  $\sec\alpha \left( \cos\left(\alpha - \frac{\pi}{2}\right) + i \sin\left(\alpha - \frac{\pi}{2}\right) \right)$

Case - II : When  $\alpha \in \left(\frac{\pi}{2}, \pi\right]$

$$|z| = \sqrt{\tan^2\alpha + 1} = \sqrt{\sec^2\alpha} = |\sec\alpha| = -\sec\alpha$$

Let  $\beta$  be acute angle given by  $\tan\beta = \frac{|\operatorname{Im}(z)|}{|\operatorname{Re}(z)|}$ .

$$\tan\beta = \frac{1}{|\tan\alpha|} = |\cot\alpha| = -\cot\alpha = \tan\left(\alpha - \frac{\pi}{2}\right)$$

$$\Rightarrow \beta = \alpha - \frac{\pi}{2}$$

As  $z$  is represented by a point in third quadrant.

$$\therefore \arg(z) = \pi + \beta = \frac{\pi}{2} + \alpha.$$

So polar form of  $z$  is  $-\sec\alpha \left( \cos\left(\frac{\pi}{2} + \alpha\right) + i \sin\left(\frac{\pi}{2} + \alpha\right) \right)$ .

Let  $z = (1 - \sin \alpha) + i \cos \alpha$

Since sine and cosine are periodic functions with period  $2\pi$

So, let us take  $\alpha$  lying in the interval  $[0, 2\pi]$ .

Now,  $z = (1 - \sin \alpha) + i \cos \alpha$

$$\Rightarrow |z| = \sqrt{(1 - \sin \alpha)^2 + \cos^2 \alpha} = \sqrt{2 - 2 \sin \alpha} = \sqrt{2} \sqrt{1 - \sin \alpha}$$

$$\Rightarrow |z| = \sqrt{2} \sqrt{\left(\cos \frac{\alpha}{2} - \sin \frac{\alpha}{2}\right)^2} = \sqrt{2} \left| \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right|$$

Let  $\beta$  be acute angle given by  $\tan \beta = \frac{|\operatorname{Im}(z)|}{|\operatorname{Re}(z)|}$ .

$$\tan \beta = \frac{|\cos \alpha|}{|1 - \sin \alpha|} = \frac{|\cos \alpha|}{|1 - \sin \alpha|} = \frac{\left| \cos^2 \frac{\alpha}{2} - \sin^2 \frac{\alpha}{2} \right|}{\left( \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right)^2} = \frac{\left| \cos \frac{\alpha}{2} + \sin \frac{\alpha}{2} \right|}{\left| \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right|}$$
$$\Rightarrow \tan \beta = \left| \frac{1 + \tan \frac{\alpha}{2}}{1 - \tan \frac{\alpha}{2}} \right| = \left| \tan \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) \right|$$

Following cases arise:

Case I: When  $0 \leq \alpha < \frac{\pi}{2}$

$$\cos \frac{\alpha}{2} > \sin \frac{\alpha}{2} \text{ and } \frac{\pi}{4} + \frac{\alpha}{2} \in \left[ \frac{\pi}{4}, \frac{\pi}{2} \right)$$

$$\therefore |z| = \sqrt{2} \left( \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right)$$

$$\text{and, } \tan \beta = \left| \tan \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) \right| = \tan \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) \Rightarrow \beta = \frac{\pi}{4} + \frac{\alpha}{2}$$

Clearly,  $z$  lies in the first quadrant.

$$\therefore \arg(z) = \frac{\pi}{4} + \frac{\alpha}{2}$$

So polar form of  $z$  is  $\sqrt{2} \left( \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right) \left( \cos \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) + i \sin \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) \right)$

Case II: When  $\frac{\pi}{2} < \alpha < \frac{3\pi}{2}$

$$\cos \frac{\alpha}{2} < \sin \frac{\alpha}{2} \text{ and } \frac{\pi}{4} + \frac{\alpha}{2} \in \left(\frac{\pi}{2}, \pi\right)$$

$$\therefore |z| = \sqrt{2} \left| \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right| = -\sqrt{2} \left( \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right)$$

$$\text{and, } \tan \beta = \left| \tan \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) \right| = -\tan \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) = \tan \left\{ \pi - \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) \right\} = \tan \left( \frac{3\pi}{4} - \frac{\alpha}{2} \right)$$

$$\Rightarrow \beta = \frac{3\pi}{4} - \frac{\alpha}{2}$$

Since  $1 - \sin \alpha > 0$  and  $\cos \alpha < 0$ .

Clearly,  $z$  lies in the fourth quadrant.

$$\therefore \arg(z) = -\beta = \frac{\alpha}{2} - \frac{3\pi}{4}$$

$$\text{So polar form of } z \text{ is } -\sqrt{2} \left( \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right) \left( \cos \left( \frac{\alpha}{2} - \frac{3\pi}{4} \right) + i \sin \left( \frac{\alpha}{2} - \frac{3\pi}{4} \right) \right)$$

Case III: When  $\frac{3\pi}{2} < \alpha < 2\pi$

$$\cos \frac{\alpha}{2} < \sin \frac{\alpha}{2} \text{ and } \frac{\pi}{4} + \frac{\alpha}{2} \in \left(\pi, \frac{5\pi}{4}\right)$$

$$\therefore |z| = \sqrt{2} \left| \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right| = -\sqrt{2} \left( \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right)$$

$$\text{and, } \tan \beta = \left| \tan \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) \right| = \tan \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) = -\tan \left\{ \pi - \left( \frac{\pi}{4} + \frac{\alpha}{2} \right) \right\} = \tan \left( \frac{\alpha}{2} - \frac{3\pi}{4} \right)$$

$$\Rightarrow \beta = \frac{\alpha}{2} - \frac{3\pi}{4}$$

Clearly,  $\operatorname{Re}(z) < 0$  and  $\operatorname{Im}(z) > 0$ .

So,  $z$  lies in the first quadrant.

$$\therefore \arg(z) = \beta = \frac{\alpha}{2} - \frac{3\pi}{4}$$

$$\text{So polar form of } z \text{ is } -\sqrt{2} \left( \cos \frac{\alpha}{2} - \sin \frac{\alpha}{2} \right) \left( \cos \left( \frac{\alpha}{2} - \frac{3\pi}{4} \right) + i \sin \left( \frac{\alpha}{2} - \frac{3\pi}{4} \right) \right).$$

$$\text{Let } z = \frac{1-i}{\cos \frac{\pi}{3} + i \sin \frac{\pi}{3}} = \frac{1-i}{\frac{1}{2} + i \frac{\sqrt{3}}{2}} = \frac{2-2i}{1+i\sqrt{3}} = \frac{(2-2i)(1-i\sqrt{3})}{(1+i\sqrt{3})(1-i\sqrt{3})} =$$

$$\frac{(2-2\sqrt{3}) - i(2\sqrt{3}+2)}{4} = \frac{(1-\sqrt{3})}{2} - i \frac{(\sqrt{3}+1)}{2}$$

$$|z| = \sqrt{\frac{(1-\sqrt{3})^2}{4} + \frac{(\sqrt{3}+1)^2}{4}} = \sqrt{\frac{8}{4}} = \sqrt{2}$$

Let  $\beta$  be acute angle given by  $\tan \beta = \frac{|\text{Im}(z)|}{|\text{Re}(z)|}$ .

$$\tan \beta = \frac{\left| \frac{(\sqrt{3}+1)}{2} \right|}{\left| \frac{(1-\sqrt{3})}{2} \right|} = \frac{|-(\sqrt{3}+1)|}{|1-\sqrt{3}|} = |2+\sqrt{3}| = \tan\left(\frac{7\pi}{12}\right)$$

$$\Rightarrow \beta = \frac{7\pi}{12}$$

$Z$  is represented by a point in second quadrant.

So polar form of  $z$  is  $\sqrt{2} \left( \cos \frac{7\pi}{12} - i \sin \frac{7\pi}{12} \right)$ .

$$|z_1| = |z_2|$$

Let  $\arg(z_1) = \theta$

$\therefore \arg(z_2) = \pi - \theta$

In polar form,  $z_1 = |z_1|(\cos \theta + i \sin \theta)$ .....(i)

$$z_2 = |z_2|(\cos(\pi - \theta) + i \sin(\pi - \theta))$$

$$= |z_2|(-\cos \theta + i \sin \theta)$$

$$= -|z_2|(\cos \theta - i \sin \theta)$$

Finding conjugate of

$$\bar{z}_2 = -|z_2|(\cos \theta + i \sin \theta)$$
.....(ii)

(i)/(ii) is equal to

$$\frac{z_1}{z_2} = -\frac{|z_1|(\cos \theta + i \sin \theta)}{|z_2|(\cos \theta + i \sin \theta)}$$

$$\frac{z_1}{z_2} = -\frac{|z_1|}{|z_2|} \quad [\because |z_1| = |z_2|]$$

$$\frac{z_1}{z_2} = -1$$

$$z_1 = -z_2$$

$$z_1 = -\bar{z}_2$$

Hence Proved.

$z_1, z_2$  are conjugates implies  $z_2 = \bar{z}_1$

$z_3, z_4$  are conjugates implies  $z_4 = \bar{z}_3$

Also we know that  $\arg(z_1) + \arg(\bar{z}_1) = 0$

$$\arg\left(\frac{z_1}{z_4}\right) + \arg\left(\frac{z_2}{z_3}\right)$$

$$= \arg(z_1) - \arg(z_4) + \arg(z_2) - \arg(z_3) \quad [\because \arg\left(\frac{z_1}{z_2}\right) = \arg(z_1) - \arg(z_2)]$$

$$= \arg(z_1) - \arg(\bar{z}_3) + \arg(\bar{z}_1) - \arg(z_3)$$

$$= \arg(z_1) + \arg(\bar{z}_1) - \arg(\bar{z}_3) - \arg(z_3)$$

$$= \arg(z_1) + \arg(\bar{z}_1) - [\arg(\bar{z}_3) + \arg(z_3)] \quad [\because \arg(z_1) + \arg(\bar{z}_1) = 0]$$

$$= 0 + 0 = 0$$
